```

LIBRARY

Streaming Archive Library (libarchive, -larchive)

SYNOPSIS

```
#include <archive.h>
struct archive *
archive_read_disk_new(void);
int
archive_read_disk_set_symlink_logical(struct archive *);
archive_read_disk_set_symlink_physical(struct archive *);
archive_read_disk_set_symlink_hybrid(struct archive *);
int
archive_read_disk_gname(struct archive *, gid_t);
archive_read_disk_uname(struct archive *, uid_t);
int
archive read disk set gname lookup(struct archive *, void *,
    const char *(*lookup)(void *, gid_t),void (*cleanup)(void *));
int
archive_read_disk_set_uname_lookup(struct archive *, void *,
    const char *(*lookup)(void *, uid_t),void (*cleanup)(void *));
archive_read_disk_set_standard_lookup(struct archive *);
archive_read_disk_entry_from_file(struct archive *,
    struct archive_entry *, int fd, const struct stat *);
int
archive_read_close(struct archive *);
archive_read_finish(struct archive *);
archive_read_free(struct archive *);
```

DESCRIPTION

These functions provide an API for reading information about objects on disk. In particular, they provide an interface for populating struct archive_entry objects.

archive read disk new()

Allocates and initializes a struct archive object suitable for reading object information from disk.

archive_read_disk_set_symlink_logical(),

```
archive_read_disk_set_symlink_physical(),
archive_read_disk_set_symlink_hybrid()
```

This sets the mode used for handling symbolic links. The "logical" mode follows all symbolic links. The "physical" mode does not follow any symbolic links. The "hybrid" mode currently behaves identically to the "logical" mode.

archive read disk gname(), archive read disk uname()

Returns a user or group name given a gid or uid value. By default, these always return a NULL string.

archive_read_disk_set_gname_lookup(), archive_read_disk_set_uname_lookup()

These allow you to override the functions used for user and group name lookups. You may also provide a void * pointer to a private data structure and a cleanup function for that data. The cleanup function will be invoked when the struct archive object is destroyed or when new lookup functions are registered.

archive_read_disk_set_standard_lookup()

This convenience function installs a standard set of user and group name lookup functions. These functions use getpwuid(3) and getgrgid(3) to convert ids to names, defaulting to NULL if the names cannot be looked up. These functions also implement a simple memory cache to reduce the number of calls to getpwuid(3) and getgrgid(3).

archive_read_disk_entry_from_file()

Populates a struct archive_entry object with information about a particular file. The archive_entry object must have already been created with archive_entry_new(3) and at least one of the source path or path fields must already be set. (If both are set, the source path will be used.)

Information is read from disk using the path name from the struct archive_entry object. If a file descriptor is provided, some information will be obtained using that file descriptor, on platforms that support the appropriate system calls.

If a pointer to a struct stat is provided, information from that structure will be used instead of reading from the disk where appropriate. This can provide performance benefits in scenarios where struct stat information has already been read from the disk as a side effect of some other operation. (For example, directory traversal libraries often provide this information.)

Where necessary, user and group ids are converted to user and group names using the currently registered lookup functions above. This affects the file ownership fields and ACL values in the struct archive_entry object.

archive_read_close()

Does nothing for archive_read_disk handles.

${\tt archive_read_finish}()$

This is a deprecated synonym for archive_read_free().

archive read free()

Invokes **archive_read_close()** if it was not invoked manually, then releases all resources. More information about the *struct archive* object and the overall design of the library can be found in the libarchive(3) overview.

EXAMPLE

The following illustrates basic usage of the library by showing how to use it to copy an item on disk into an archive

```
biov
file_to_archive(struct archive *a, const char *name)
 char buff[8192];
 size t bytes read;
  struct archive *ard;
  struct archive_entry *entry;
  int fd;
  ard = archive read disk new();
  archive read disk set standard lookup(ard);
  entry = archive entry new();
  fd = open(name, O_RDONLY);
  if (fd < 0)
     return;
 archive_entry_copy_pathname(entry, name);
  archive read disk entry from file(ard, entry, fd, NULL);
  archive_write_header(a, entry);
  while ((bytes read = read(fd, buff, sizeof(buff))) > 0)
    archive_write_data(a, buff, bytes_read);
  archive_write_finish_entry(a);
  archive read free(ard);
  archive entry free(entry);
}
```

RETURN VALUES

Most functions return **ARCHIVE_OK** (zero) on success, or one of several negative error codes for errors. Specific error codes include: **ARCHIVE_RETRY** for operations that might succeed if retried, **ARCHIVE_WARN** for unusual conditions that do not prevent further operations, and **ARCHIVE_FATAL** for serious errors that make remaining operations impossible.

archive_read_disk_new() returns a pointer to a newly-allocated struct archive object or NULL if the allocation failed for any reason.

archive_read_disk_gname() and archive_read_disk_uname() return const char * pointers to
the textual name or NULL if the lookup failed for any reason. The returned pointer points to internal storage
that may be reused on the next call to either of these functions; callers should copy the string if they need to
continue accessing it.

ERRORS

Detailed error codes and textual descriptions are available from the **archive_errno**() and **archive_error_string**() functions.

HISTORY

The **libarchive** library first appeared in FreeBSD 5.3. The **archive_read_disk** interface was added to **libarchive 2.6** and first appeared in FreeBSD 8.0.

AUTHORS

The **libarchive** library was written by Tim Kientzle (kientzle@FreeBSD.org).

BUGS

The "standard" user name and group name lookup functions are not the defaults because getgrgid(3) and getpwuid(3) are sometimes too large for particular applications. The current design allows the application author to use a more compact implementation when appropriate.

The full list of metadata read from disk by **archive_read_disk_entry_from_file**() is necessarily system-dependent.

The archive_read_disk_entry_from_file() function reads as much information as it can from disk. Some method should be provided to limit this so that clients who do not need ACLs, for instance, can avoid the extra work needed to look up such information.

This API should provide a set of methods for walking a directory tree. That would make it a direct parallel of the archive_read(3) API. When such methods are implemented, the "hybrid" symbolic link mode will make sense.
